

# Design of comparative experiments

ABB lecture series – lecture 1

# Designing comparative experiments

- Comparative experiments estimate differences in response between treatments
- An experiment has
  - ▶ Experimental factors
  - ▶ Experimental units
  - ▶ A method to assign the experimental factors to the experimental units
  - ▶ Responses

# Experimental factors

- Usually a classification factor
  - ▶ Genotype or variety
  - ▶ Treatment
  - ▶ Temperature
  - ▶ Dosage
  - ▶ Time
  - ▶ ...

# Experimental units

That object to which a treatment or condition is **independently** applied.

- An experimental unit should be as homogeneous as possible

- ▶ Eg. Explants cultured in test tubes containing 15 ml of regeneration medium. There are 2 types of medium (=experimental factor). There are 24 tubes per treatment. All tubes are completely randomly placed in the rack. The number of shoots per explant was recorded 12 weeks after culture initiation. The experimental unit is the test tube.

# Experimental units

## Subsampling (or pseudoreplication)

- ▶ Cotyledons of 1 genotype are arranged in 3 plates with medium A and in 3 plates with medium B. What is the experimental unit now?
- ▶ Measurements on different plant parts within a plant
- ▶ The measurements are not independent of each other. The statistical analysis must **account for the correlation** between measurements done on the same plate

# Randomization

- Randomization is the way of assigning subjects to treatment groups. All experimental units should have an equal chance of being assigned to any of the treatment groups.
- Randomization protects against **confounding**
  - ▶ Confounding occurs when the effect of one factor cannot be distinguished from the effect of another factor
- Randomization of measurements: measuring first all treatment 1 units, and then all treatment 2 units will introduce serial dependency or autocorrelation in the data

# Confounding examples

- Comparing different genotypes: all plates should contain all genotypes!

- Confounding of treatment with experimental units
  - ▶ Treatment-plate confounding

- ▶ Treatment-block confounding

# Confounding examples

- 20 B73 maize plants were grown under normal water conditions and 20 under drought conditions according to a CRD design. Metabolomics data were collected but first all watered plants were analysed and then all drought plants.

# Performing a randomization

- Physical randomisation
  - ▶ Coin tosses
  - ▶ Rolls of a die
  - ▶ Tickets in a hat
- Numerical randomisation
  - ▶ Using random number generators with computer software
- Example:
  - ▶ assigning 16 plants to two treatments
  - ▶ Number the plants
  - ▶ Sample from 1 to 16 without replacement
  - ▶ 16 9 3 14 11 6 4 15 5 2 1 7 12 8 10 13
  - ▶ Assign treatment A to plants 16 9 3 14 11 6 4 15
  - ▶ Assign treatment B to plants 5 2 1 7 12 8 10 13

# Types of outcome

- Continuous outcome
  - ▶ Eg. area, height, weight, length, biomass
- Count data
  - ▶ Eg. number of chloroplast cells, nr of seeds, nr of ovules, nr of leaves, nr of lateral roots
  - ▶ Count rate data: lateral root density
- Binary data:
  - ▶ Eg. germinated or not, dead or not, peptide presence
- Ordinal data:
  - ▶ Eg. ovule stages, disease stage, bud formation stage

# Types of outcome

- Repeated measurements

- ▶ Multiple measurements on the same experimental unit

- ▶ Examples:

- Leaf area measured on 2 leaves from the same plant
    - Root length measured on seedlings grown on the same plate
    - Yield measured on maize plants from the same block

} Hierarchical or clustered data

- Leaf area measured over time on the same plant

} Longitudinal data

- ▶ Analysed with mixed models;

- Continuous outcome: linear mixed model
    - Counts, binary, ordinal: generalized mixed models

| Outcome Variable                                    | Are the observations independent or correlated?                                               |                                                                                    | Alternatives (assumptions violated)                                                                               |
|-----------------------------------------------------|-----------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
|                                                     | independent                                                                                   | correlated                                                                         |                                                                                                                   |

# Arrangement of the data

- All data on the same subject should be on one row
- More examples on the psb wiki
- Follow name conventions for the headers
- Use . as decimal separator
- Provide the meta data

|    | A     | B      | C    | D              | E     | F      | G      | H       | I        |

# A good experimental design must...

- ▶ avoid systematic error (=bias) -> randomize
- ▶ be precise. Precision depends on
  - the size of the random errors on the responses
  - the number of experimental units
  - the design
- ▶ allow estimation of the random (=experimental) error
  - *i.e.* the variability in the outcome among **identically** and **independently** treated experimental units
- ▶ have broad validity
  - The experimental units should reflect the population about which we wish to draw inference.
- ▶ be sufficiently powerful to detect treatment effects of biological significance -> adequate number of replications

***A wise experimenter will consider the analysis when planning an experiment***

# Experimental error

- describes the variability in the outcome among **identically** and **independently** treated experimental units
- Minimize experimental error by
  - ▶ Selecting experimental units which are as homogeneous as possible
  - ▶ Taking measurements in as uniform as possible. Be aware of how the following can introduce variability:
    - Person-to-person differences in how measurements are taken
    - Within person differences (how tired were you when collecting the measurements?)
    - Run-to-run differences in how measurements are recorded
    - Differences in equipment: pipettes, microtiter plates,...
    - Differences in supplies (soils, growth media,...)

# Experimental error

- Minimize experimental error by
  - ▶ Controlling the environment to be as uniform as possible (temperature, humidity, light, ...)
  - ▶ Taking the same seed stock
  - ▶ Harvesting at the same time
  - ▶ Studies that take time to complete should keep track of the days/weeks/months on which measurements are collected (temporal, seasonal variability)
  - ▶ Studies involving repeated measurements on each experimental unit need to keep track of which measurements came from which unit.

# Replication

- *i.e.* assigning several **experimental units** to each treatment group
- Replication allows the researcher to demonstrate **reproducibility**
- Replication guards against an experiment failing (plants died, seed did not germinate,...)
- Replication allows to measure experimental error
- Replication improves the precision of the treatment effect estimate
- How many replications should we use?
  - ▶ Perform sample size study

# Power and sample size

- Sample size analysis
  - ▶ Prior knowledge necessary on treatment effects, error variance, type I error rate and power
- Power analysis
  - ▶ Prior knowledge necessary on treatment effects, error variance, type I error rate and sample sizes
- For complex experiments no closed formulas available, simulation studies are necessary.

# Generalizability

- The conclusions we draw from an experiment are directly applicable to the experimental units used in that experiment
  - ▶ If the units were randomly selected from some population of units, then the conclusions can be applied to that population.
  - ▶ If the conclusions are applied to any other group of potential experimental units, then we are extrapolating. This may not be valid.

# Climate chamber experiments

- Weiss chamber
  - ▶ Thermostatic chamber
- Lovibond
  - ▶ Thermostatic chamber

# Climate chamber experiments

- The treatment condition (temperature or light intensity) is randomly applied to the growth chamber, thus **the growth chamber becomes the experimental unit**.
- Pots, petri-dishes, trays, plants included within a growth chamber are considered subsamples and should not be treated as true replicates.
- To provide **valid replications** when the number of growth chambers are limited, the experiments should be repeated by using the same growth chamber with different randomly assigned treatment levels.

# Climate chamber example

- 4 growth chambers
- 1 tray/growth chamber
- 2 genotypes/tray
  - ▶ Col: 24 plants
  - ▶ Transgene: 24 plants
- 16 plants/gt/tray selected
- 1 ovary/plant
- Count the ovules/ovary and decide on stage (5 stages)
  - ▶ problem of no fixed sample size
  - ▶ Problem of complete separation
- Unbalanced data
- Clustered data
- Proportional odds model

# Growth chamber experiments

- Commonly used experimental units:
  - ▶ Individual pots
  - ▶ Trays
  - ▶ Plates
- Recommended to measure also air temperature, humidity, moisture variation.
- Use suitable blocking and possibly additional covariates
  - ▶ Shelf to shelf variation
  - ▶ position on the shelf (under the light, close to the wall, to the door,...)

# Greenhouse experiments

- Commonly used experimental units:
  - ▶ Individual pots
  - ▶ Trays
- Recommended to measure also air temperature, humidity, solar radiation, moisture variation.
- Use suitable blocking and possibly additional covariates.
  - ▶ When assigning blocks take into account known directional variation (movement of the sun)
  - ▶ ***Blocking is preferred over relocating the plants!***
    - Brien et al. Plant methods 2013

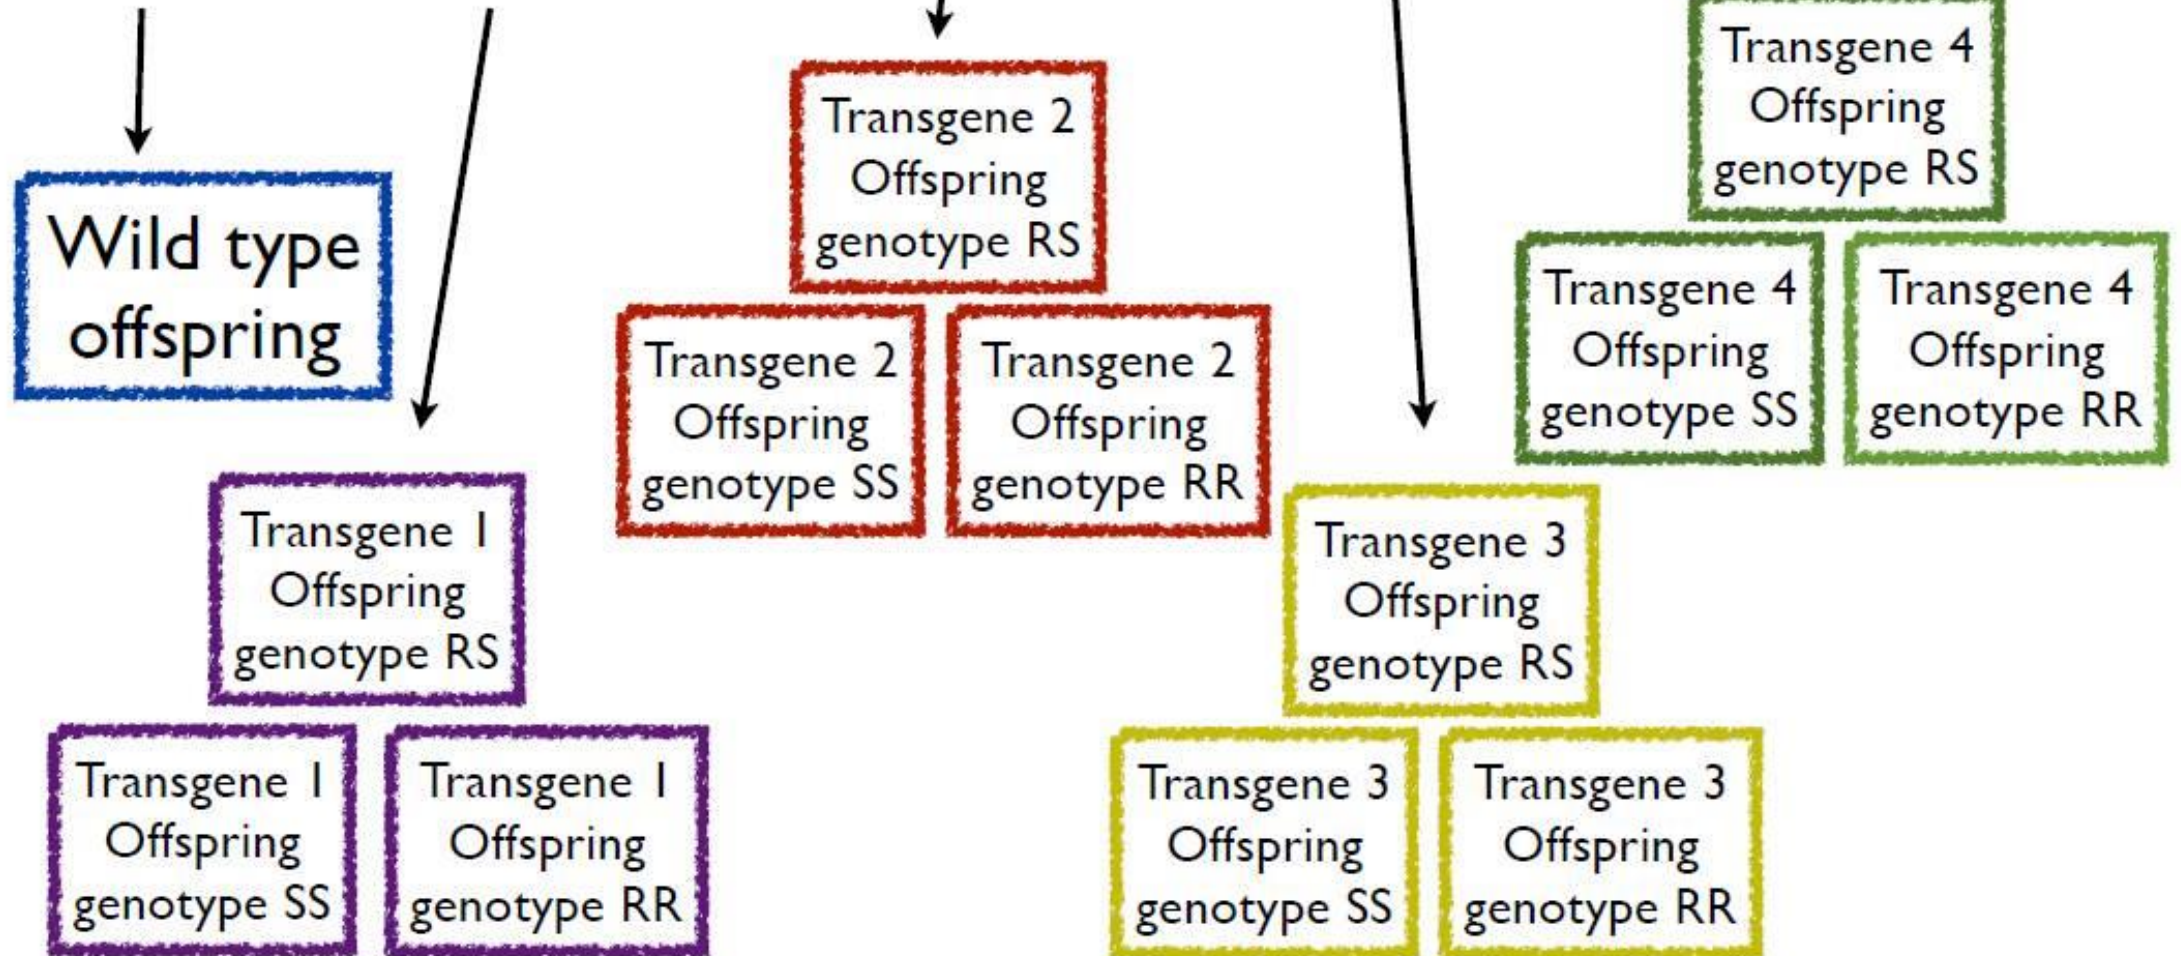

# Arabidopsis example

- A gene from a related plant is introduced into the genomes of 4 separate Arabidopsis Col-o plants.
- Each of these plants is the progenitor of a transgenic line.
- A wild-type Col-o plant is included in the experiment.
- These 5 plants represent the T<sub>1</sub> generation.
- Each T<sub>1</sub> plant is grown, self-fertilized and seed is collected.
- 25 seeds from each plant are potted individually, grown and self-fertilized. These plants are the T<sub>2</sub> generation. Fruit length is measured from 10 fruit of each T<sub>2</sub> plant

T<sub>1</sub>

Self-fertilize, grow, plant individual seeds, grow

T<sub>2</sub>

# Arabidopsis example from the lab

- T2 plants are sown over 5 plates (unknown genotype Aa, aa or AA (characterised under bino).
  - ▶ As a result: highly unbalanced over the trays
- 5 lines of T2 plants (1 line is the ctrl line)
- 2 conditions
- Y measured over time (longitudinal data)
- Measure Y on 20 to 30 plants/line\*condition

# High-throughput phenotyping platforms

- start with a **uniformity trial**
  - ▶ All blocks receive the same treatment
  - ▶ To investigate heterogeneity on the platform/field
  - ▶ Spatially correlated data
    - Spatial analysis is required (possible within the mixed model framework)

# Field experiments

- Suitable for conducting
  - ▶ Yield trials
  - ▶ Genotype screening
  - ▶ Compare irrigation, nutrition, pest, disease, weed control,...
- **Multiyear** studies to investigate the interaction between the treatment and the year to remove confounding effects of climatic variation.
- **Multisite** studies in a given year to evaluate the treatment effects across different sites and to investigate the treatment-site interaction to remove confounding effects of soil variation.

# Field experiments

- Highly recommended:
  - ▶ Blocking along the field variability gradient
  - ▶ Measuring additional continuous covariates
- Common designs
  - ▶ Strip-plot design
  - ▶ Randomized complete block design (RCB)
  - ▶ Split-plot design
  - ▶ Factorial design
  - ▶ Row-column design

# Strip-plot design

- 3 varieties each planted in 8 rows

# Randomized complete block design

|       |   |   |   |       |   |   |   |       |   |   |   |       |   |   |   |
|-------|---|---|---|-------|---|---|---|-------|---|---|---|-------|---|---|---|

# Row-column design

- Latin square
  - ▶ Complete row-column design
  - ▶ When a gradient in 2 directions is expected

The diagram illustrates a 4x4 Latin square design. A vertical arrow on the left indicates a 'Temperature gradient' from 'Low' at the bottom to 'High' at the top. A horizontal arrow at the top indicates a 'Light intensity' gradient from 'Low' on the left to 'High' on the right. The four treatments (A, B, C, D) are arranged in a 4x4 grid such that each treatment appears exactly once in each row and each column.

|                      |      | Light intensity |   |      |   |
|----------------------|------|-----------------|---|------|---|
|                      |      | Low             |   | High |   |
| Temperature gradient | High | C               | D | A    | B |
|                      |      | D               | B | C    | A |
|                      |      | B               | A | D    | C |
|                      | Low  | A               | C | B    | D |

# Row-column design

- Incomplete row-columns
  - ▶ 7 treatments arranged in 4 rows and 7 columns

|   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|
| 1 | 3 | 5 | 7 | 2 | 4 | 6 |
| 2 | 1 | 7 | 5 | 3 | 6 | 4 |
| 3 | 6 | 2 | 4 | 7 | 5 | 1 |
| 4 | 5 | 6 | 3 | 1 | 2 | 7 |

- General row-column setting
  - ▶  $v$  treatments arranged in a  $p \times q$  array

# Incomplete block design

- Occurs when not all treatments are allocated in every block

BIB with 5 treatments, 10 blocks of size  $k=3$

Balanced:

- Each treatment is replicated 6 times
- each pair of treatments appears 3 times within a block

IB designs are used for GWAS applications

Dedicated software is used to plan the design

- SAS proc optex
- cycDesignN

| block | treatment |   |   |   |   |
|-------|-----------|---|---|---|---|
| block | A         | B | C | D | E |
| 1     |           | x | x |   | x |
| 2     | x         |   |   | x | x |
| 3     |           | x |   | x | x |
| 4     |           |   | x | x | x |
| 5     | x         | x |   | x |   |
| 6     | x         | x |   |   | x |
| 7     | x         | x | x |   |   |
| 8     |           | x | x | x |   |
| 9     | x         |   | x |   | x |
| 10    | x         |   | x | x |   |

# Statistical analysis

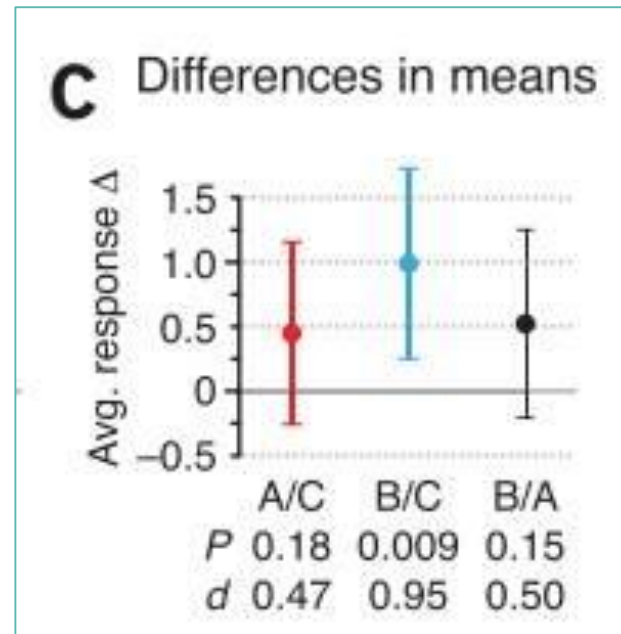

- What do you need to know before beginning an analysis?
  - ▶ Research question
  - ▶ How were the measurements recorded?
  - ▶ How were the treatments assigned?
  - ▶ What was the experimental unit?
  - ▶ What was the measurement unit?
  - ▶ Was the study carried out in the way it was originally designed?

# A good analysis should...

- Involve data cleaning
- Involve data exploration
- Use an appropriate statistical method
- Verify that the method's assumptions are met
- Describe the results in appropriate language

# Report example

- Reporting a single factor experiment with post-hoc comparisons
  - Krzywinski and Altman, Nature methods, 2014

# P-values and effect sizes

- A p-value is easily misinterpreted.
  - ▶ A low p-value does not necessarily mean that a finding is of major biological interest. If the sample size is large enough, a tiny effect can result in a low p-value.

# *p*-hacking and *p*-harking

- *p*-hacking is the misreporting of true effect sizes. It occurs when researchers try out several statistical analyses and then selectively report those that produce significant results.
  - ▶ Eg. recording many response variables and deciding which to report postanalysis.
  - ▶ Synonyms: data-dredging, snooping, fishing, significance-chasing and double-dipping
- *p*-HARKing is the acronym for '**h**ypothesizing **a**fter the **r**esults are **k**nown'. It indicates the phenomenon of constructing hypotheses after the data are analyzed, suggesting that only one hypothesis was tested while many were contemplated.

# Balancedness

- Balance i.e. all factor-level combinations (cells) have the same amount of replication
- Imbalance destroys orthogonality ie the computation of the SS of one term does not depend on what other terms there are in the model.

# Balancedness

- Balanced data are less susceptible to the effects of nonnormality and nonconstant variance
- Exact statistical methods are not available for imbalanced data, one must resort to approximate methods
- Special case: compare  $g$  treatments to a control treatment:

$$n_c = n_t \sqrt{g - 1}$$

with  $n_c$  sample size control group

and  $n_t$  sample size treatment groups

# Consequences of imbalance

- In more complex models, some null hypotheses have no exact F-test. Approximate tests are used and the denominator degrees of freedom must be adjusted with the Satterthwaite approach.
- Unbalanced data lead to complicated forms.
  - ▶ A preferred method over the ANOVA method is based on the restricted maximum likelihood (REML) approach
  - ▶ Wald-type F-tests must be used
  - ▶ Denominator df are estimated with the Kenward-Roger method
  - ▶ Adjusted means (least square means) must be used instead of arithmetic means. Lsmeans are identical to arithmetic means in the balanced case only.
  - ▶ Variance-covariance matrix can be not positive-definite

# Missing factor level combinations

- The problems of unbalanced data are increased when there is no data for one or more of the factor-level combinations.
  - ▶ some of the least squares means are not estimable. Because statistical software such as SAS/STAT PROC MIXED will not compute least squares means (LSMs) that are inestimable, obtaining desired estimates and comparisons may become difficult.

# Missing factor level combinations

- Possible solutions:
  - ▶ Truncating data to create a complete data structure
    - Loss of power
  - ▶ Fit unsaturated models
    - effects have been eliminated from the model even though they may account for a large portion of the response variability.
    - Consequently, estimates of fixed effects remaining in the model are unadjusted for eliminated effects and may be biased, particularly when data are unbalanced.
    - estimates of the covariance components are consistent only when the mean is correctly specified
